

A review of the species of *Crenicichla* (Teleostei: Cichlidae) from the Atlantic coastal rivers of southeastern Brazil from Bahia to Rio Grande do Sul States, with descriptions of three new species

Sven O. Kullander* and Carlos A. Santos de Lucena**

Six species of *Crenicichla*, three of which are new, are recognized from the Atlantic coastal rivers of southeastern Brazil from the state of Bahia south to the state of Rio Grande do Sul: *C. mucuryna* (upper rio Mucuri, Minas Gerais), *C. lacustris* (from the rio Paraíba do Sul north to the rio Buranhem, Bahia), *C. iguapina*, new species (rio Ribeira de Iguape), *C. tingui*, new species (from the rio Itapocu to the rio Nhundiaquara drainage), *C. maculata*, new species (lagoa dos Quadros, rio Maquiné, Rio Grande do Sul to rio Itapocu, Santa Catarina drainages), and *Crenicichla punctata* (laguna dos Patos basin). *Crenicichla biocellata* is a synonym of *C. lacustris*; and also a secondary homonym of *Sparus biocellatus*, a synonym of *C. saxatilis*. *Crenicichla dorsocellata* is also a synonym of *C. lacustris*.

Seis espécies de *Crenicichla*, sendo três novas, são reconhecidas dos rios costeiros do sudeste brasileiro, desde o estado da Bahia para o sul, até o estado do Rio Grande do Sul: *C. mucuryna* (parte superior do rio Mucuri, Minas Gerais), *C. lacustris* (do rio Paraíba do Sul para o norte até o rio Buranhem, Bahia), *C. iguapina*, esp. nova (do rio Ribeira de Iguape), *C. tingui*, esp. nova (das drenagens do rio Itapocu, Santa Catarina ao rio Nhundiaquara, Paraná), *C. maculata*, esp. nova (lagoa dos Quadros, rio Maquiné, Rio Grande do Sul ao rio Itapocu, Santa Catarina) e *Crenicichla punctata* (sistema da laguna dos Patos). *Crenicichla biocellata* e *C. dorsocellata* são consideradas sinônimos de *C. lacustris*. A primeira é também um homônimo secundário de *Sparus biocellatus* que por sua vez é sinônimo de *Crenicichla saxatilis*.

Key words: *Crenicichla tingui*, *Crenicichla iguapina*, *Crenicichla maculata*, Systematics, Conservation.

Introduction

The cichlid genus *Crenicichla*, comprising 74 valid species (Kullander, 2003), is currently recognized as the most species rich genus of cichlids. It is found over most of tropical and subtropical cis-Andean South America. The genus has been revised repeatedly (Pellegrin, 1904; Regan, 1905, 1913; Ploeg, 1991), and a large number of papers have added new species or revise smaller units, most recently Lucena & Azevedo (1989), Lucena & Kullander (1992), and Kullander (1990a,b; 1991; 1997).

Six species of *Crenicichla* have been described from the rivers draining to the Atlantic coast of southeastern Brazil between the States of Rio Grande do Sul (laguna dos Patos system) and Bahia (city of Salvador), viz. *Crenicichla lacustris* Castelnau (1855) from “Dique, ou étang près de Bahia;” *C. punctata* Hensel (1870) from the lago Guaíba and *C. polysticta* Hensel (1870) from the rio Cadeia, both localities in Rio Grande

do Sul; *C. dorsocellata* Haseman (1911) from Campos, rio Paraíba do Sul, State of Rio de Janeiro; *C. biocellata* Ihering (1914) from Porto Cachoeiro (now Santa Leopoldina), State of Espírito Santo, and *C. mucuryna* Ihering (1914) from the rio Todos os Santos, a tributary of the rio Mucuri in the State of Minas Gerais.

These six nominal species have for the most part been synonymized under *C. lacustris* (e.g., Ploeg, 1991), or treated as a systematically poorly understood *C. lacustris* group (e.g., Kullander, 1982), vaguely diagnosed by the absence of pterotic serrations (vs. presence in *C. wallacii* group), moderate scale counts, 47-70 (vs. 90 or more in the *C. lugubris* and *C. acutirostris* groups), presence of red belly in breeding females and absence of humeral ocellus (vs. present in *C. saxatilis* group), 3 to 5 rows of depressible teeth and without vertical bars in any ontogenetic stage (vs. often with fewer, more firmly implanted teeth and always with a colour pattern

consisting of vertical bars from juvenile to adult in the *C. reticulata* group); serrated preopercular margin (*vs.* smooth in *C. missioneira* group; *C. celidochilus* Casciotta, 1987 is tentatively included in this group by Lucena & Kullander, 1992), maxilla just reaching to the vertical anterior of orbit (*vs.* beyond the same vertical in *C. scottii* group), and predorsal scales cycloid and normal size eyes (*vs.* ctenoid predorsal scales and extremely large eyes in *C. macrophthalma* Heckel, 1840). Besides the nominal species cited above, Ploeg (1991) includes *C. niederleini* (Holmberg, 1899); *C. jupiaensis* Britski & Luengo, 1968; *C. iguassuensis* Haseman, 1911; *C. jaguarensis* Haseman, 1911, and *C. haroldoi* Luengo & Britski, 1974 in the *C. lacustris* group.

Lucena & Kullander (1992) demonstrated that the *lacustris* group as hitherto understood is not monophyletic, and Lucena & Azevedo (1989) showed that *C. punctata* Hensel (1870), long considered a synonym of *C. lacustris*, is actually a valid species. Ploeg (1991) considered *C. polysticta* to be valid, apparently overlooking Lucena & Azevedo's (1989) synonymization of *C. polysticta* with *C. punctata*.

The present paper serves to document a much greater diversity of *Crenicichla* species along the southeastern Brazilian coast than hitherto considered. Several of the species have very limited geographical distributions within areas that are among the most densely populated in Brazil and therefore may be considered as vulnerable.

Material and Methods

Measurements and counts follow Kullander (1986). The length of a specimen is given as the standard length (SL), unless otherwise specified, and is measured from the tip of the upper jaw to the middle of the base of the caudal fin. The principal scale count, E1 scales, includes the scales in the row immediately above the row that includes the lower lateral line. We refer to the dark horizontal stripe along the middle of the side as a lateral band. A dark stripe below the orbit, extending vertically or obliquely caudad across the cheek, is termed a suborbital stripe. Most species treated in this paper possess a pattern of minute dark marks, referred to as spots, occurring on the flanks, sides of the head, and unpaired fins.

Clearing and counterstaining follow the method of Taylor & Van Dyke (1985). All other material is preserved in 70-75% ethanol. Radiographies were made with a Philips MG-105 low voltage X-ray apparatus and Agfa D2 X-ray plates. Drawings were made using a drawing tube attached to a WILD M5APO stereo dissection microscope.

The lower pharyngeal tooth plate is measured as described by Barel *et al.* (1977). Because of the similarity between the species only one tooth plate description, that of *C. maculata*, is given. The local Brazilian spelling is adopted for all river and site names. Our understanding of the laguna dos Patos system follows Malabarba (1989) and includes the lagoa Mirim.

Institutional abbreviations: DBAV - Instituto de Biologia da Universidade Estadual do Rio de Janeiro, Rio de Janeiro; FMNH - Field Museum of Natural History, Chicago; MCP -

Museu de Ciências e Tecnologia, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre; MNRJ - Museu Nacional, Rio de Janeiro; MZUSP - Museu de Zoologia, Universidade de São Paulo, São Paulo; NRM - Swedish Museum of Natural History, Stockholm; NMW - Naturhistorisches Museum, Vienna; UFRJ - Departamento de Zoologia, Universidade Federal do Rio de Janeiro, Rio de Janeiro; USNM - National Museum of Natural History, Smithsonian Institution, Washington, D.C.

The order of the species descriptions follows geographically from north to south. Additional comparative materials examined are those listed in Lucena & Kullander (1992).

Results

Key to the species of *Crenicichla* from the coastal river drainages of southeastern Brazil

1. Scales in a lateral row 57-63 (modally 61); 10-12 soft dorsal fin rays; a series of narrow dark vertical stripes along sides; lateral band absent; small dark spots on flanks and sides of head absent *C. mucuryana*
(upper rio Mucuri drainage)
- 1'. Scales in a lateral row 56-75 (modally 65); 11-13 soft dorsal fin rays; narrow vertical stripes absent; prominent dark lateral band or horizontally arranged series of dark blotches present; numerous small dark spots present or absent on flanks and side of head 2
2. A series of large, partly contiguous blotches below the upper lateral line, continued as band on caudal peduncle; suborbital stripe always well developed, extending to or nearly to preopercle 3
- 2'. Series of large contiguous blotches below upper lateral line absent; dark lateral band present along middle of side from head to caudal fin, or flanks only with pattern of minute dark spots; suborbital stripe well developed, but not as above, or short 4
3. Minute dark spots present on flanks and on side of head (occasionally absent in females); ocellated blotch present in dorsal fin in females *C. punctata*
(laguna dos Patos system)
- 3'. Minute dark spots absent from side of head even if side of body is richly spotted; females never with ocellated spot in dorsal fin *Crenicichla maculata*
(laguna dos Quadros, Rio Grande do Sul north to rio Itapocu drainage, Santa Catarina).
4. Suborbital stripe well developed, extending across more than half depth of cheek *C. iguapina*
(rio Ribeira de Iguape system).
- 4'. Suborbital stripe short, restricted to orbital margin or at most extending to near middle of cheek 5
5. Males, and occasionally females, with dark (maroon or reddish in life) spots on side of head; body either with numerous minute dark spots (males) or with few or indistinct spots and with well marked lateral band (females)
..... *C. lacustris*
(rio Paraíba do Sul drainage to rio Buranhem, Bahia)

- 5°. Dark or reddish spots on side of head absent in both sexes; both lateral band and spots on side of body well marked in both sexes *C. tingui* (rio Itapocu, Santa Catarina to rio Nhundiaquara drainage, Paraná)

***Crenicichla mucuryna* Ihering**

Fig. 1

Crenicichla mucuryna Ihering, 1914: 335 (Type-locality: rio Todos os Santos, afluyente do rio Mucury).

Material examined. 32 specimens, 33.9-113.3 mm, all from Brazil, State of Minas Gerais. MZUSP 2526 (1, 113.3 mm), rio Todos os Santos, tributary of the rio Mucuri, mun. Teófilo Otoni, 1908, E. Garbe, lectotype of *C. mucuryna*; MZUSP 5385 (1, 69.9 mm), same data as lectotype, paralectotype; MZUSP 5386 (1, 110.0 mm), same data as lectotype, paralectotype; USNM 307807 (1, 84.0 mm), rio Mucuri, mun. Nanuque, 17°50'S 40°W; USNM 318226 (28, 33.9-81.5 mm), rio Mucuri about 9 km W of town of Presidente Pena along dirt road on Fazenda Gavião, mun. Presidente Pena, 17°41'S 40°55'W.

Diagnosis. A small species of *Crenicichla* of the *C. lacustris* group *sensu lato*, not known to exceed 113 mm, distinguished from all other coastal southeastern Brazilian species by presence of a row of 9-12 narrow vertical stripes along middle of side, most of which derived from doubling or tripling of vertical bars descending from dorsum *vs.* absence of narrow vertical stripes; absence of pattern of small dark scattered spots on side of body, *vs.* presence. Similar in low scale counts (E1 53-63) and color patten (narrow vertical stripes) to species of *C. lacustris* group from upper rio Paraná basin, *viz.* *C. haroldoi* (E1 scales 50-56) and *C. jaguarensis* (E1 scales 47-53), both distinguished by a long, wide suborbital stripe and a lateral band more prominent than vertical bars; *C. jupiaensis* (E1 scales 49-55) with narrow vertical bars extending all the way from dorsal-fin base to abdominal side, suborbital stripe modified into a group of spots, and caudal spot expressed as a vertical bar; and *C. niederleinii* (E1 scales 57-65), with narrow, but long suborbital stripe, and well-marked lateral band. From *C. iguassuensis*, *C. mucuryna* can be distinguished by color pattern (absence *vs.* presence of scattered dark spots on side, and presence *vs.* absence of narrow vertical stripes).

Description. Based primarily on specimens over 50 mm. Largest male 113.3 mm, largest female 65.4 mm. Measurements given in Table 1, counts in Tables 4-8. See Fig. 1 for general aspect.

Comparatively elongate, body depth 16.3-22.5% SL. Head as deep as wide. Caudal peduncle longer than deep. Snout moderately long, rounded when viewed from above, moderately pointed in lateral view. Lower jaw slightly prognathous. Ascending premaxillary process reaching to or almost to 1/3 of orbit. Maxilla reaching to vertical from anterior margin of orbit. Upper lip thick and wide, folds not continuous but cutting into symphyseal wide thickening. Postlabial skin fold margin truncate. Orbit supralateral, not visible from below, chiefly in anterior half of head. Nostrils dorsolateral, about halfway between orbit and margin of postlabial skin fold and with low tubular margin but no anterior marginal skin flap. Vertical margin of preopercle smooth or with few irregularly distributed projections.

Flank scales strongly ctenoid. All scales on head, anteriorly on back (above about anterior ¼ of lateral line), along dorsal fin base, chest, and on belly below line from lower edge of pectoral axilla to anal fin origin and along anal fin base cycloid. Predorsal scales small, superficially embedded in skin, extending forward almost to transverse frontal lateralis canal. Prepelvic scales very small, superficially embedded in skin. Cheek fully scaled or narrowly naked ventrally and anteroventrally; 6-9 scale rows below eye, embedded in skin. Interopercle naked. Circumpeduncular scale rows 10-12 dorsally, 10-14 ventrally (total 22-25 including lateral lines).

Scales between upper lateral line and dorsal fin base 8-11 anteriorly, 4 posteriorly; 3 scale rows between lateral lines. Anterior upper lateral line scales slightly larger and more elongate than adjacent scales, remaining lateral line scales nearly the same size as adjacent scales; three scales impinging on each scale of anterior part, two on each scale of posterior part of upper lateral line; 2 scales impinging on each scale of lower lateral line. Dorsal, anal, pectoral, and pelvic fins without scales. Caudal fin squamation concave, marginally extending to near middle of fin.

First dorsal spine about 1/3-1/4 length of last; spines increasing in length to last but subequal from about 10th. Soft part of dorsal fin pointed in males, rounded in females, 7th-

Upper jaw length	51	10.1	14.8	12.1	1.169	18	9.3	20.5	11.3	2.389
Lower jaw length	51	14.2	19.1	16.2	1.351	18	13.0	16.7	14.5	0.925

8th rays reaching slightly beyond base of caudal fin. Soft anal fin with rounded tip, in both sexes reaching to base of caudal fin. Caudal fin rounded. Pectoral fin rounded, reaching about halfway to anal fin. Pelvic fin inserted well posterior to vertical from pectoral axilla, with acuminate tip, second ray longest, reaching about halfway to spinous anal fin or slightly beyond; anterior margin slightly thickened.

All teeth pointed, erect or slightly recurved. Outer row of teeth distinctly larger than inner teeth and larger anteriorly than posteriorly. Upper jaw with 4-5 inner rows; outer row teeth slightly movable or fixed, inner teeth fully depressible. Lower jaw anteriorly with 3 inner rows; all teeth inclinable or depressible.

Microbranchiospines very small, easily overlooked, but present externally on 2nd-4th arches.

Coloration in alcohol. Lateral line scales light with dark brown dot distally. Neither males nor females with small dark spots on sides as in other coastal *Crenicichla* species. Dark brown preorbital stripe from orbit running anteriorly and crossing lips to lower jaw. Dark brown postorbital stripe straight from orbit to dorsal end of opercle. Nuchal markings include blackish spot little above posttemporal and dark stripe along margin of predorsal squamation above sphenotic. Suborbital stripe black, very narrow, and short, crossing only 2-3 scale rows.

Both sexes with six wide brown bars or blotches between dorsal fin base and upper lateral line; first blotch contiguous with brownish blotch below upper lateral line, remaining blotches each transforming into 2-3 narrow dark brown vertical stripes, most intense between levels of lateral lines. Another dark bar across dorsal margin of caudal peduncle, not split like preceding vertical markings. In larger males, however, dark markings on caudal peduncle separated into smaller dark spots. Narrow vertical stripes number varies between 9 and 12.

Dorsal fin in males grayish with 2-3 rows of small dark brown spots. Caudal fin with small brown, light-ringed spot between rays D1-D3, and 6-7 vertical rows of small dark spots, most intense along middle rays. Anal fin grayish, with about 3 rows of dark spots posteriorly. In females, unpaired fins

usually immaculate save for ocellar blotches, but three specimens (56.9-61.8 mm) have few dark spots on caudal fin, in one also on dorsal fin. In these females no dorsal ocellus present or fin only slightly darker in its place. Dorsal fin ocellus present in 8 females (52.7-65.8 mm) between rays 12-16, 12-17, 13-15, 13-18 (usually 13-17), deep black, ocellation varying from hyaline dorsal margin to complete hyaline ring. Caudal fin in females usually with middle portion darker than rest and caudal spot without light ring. Pelvic fins without pigmentation in both sexes.

Two juveniles, 33.9-39.5 mm, similar to adults in body and fin coloration, *i.e.* with vertical bars across sides and spotted fins.

Geographical distribution. Known only from three localities in the rio Mucuri drainage, in the upper rio Todos os Santos at Teofilo Otoni, in the rio Mucuri close to the mouth of the rio Todos os Santos, and at Nanuque (Fig. 2).

Habitat. USNM 318226 was taken in a side branch of the main river with some rapids, to 1.25 m deep, the bottom sandy, with boulders. The surroundings were pasture with remnants of gallery forest and scattered inga trees.

Notes. *Crenicichla mucuryna* is different in overall morphology and color pattern from all coastal species of *Crenicichla* treated in this paper. It completely lacks the pattern of small dark spots covering the body and often the side of the head in one or both sexes that characterize the remaining coastal species. Instead it has a conspicuous pattern of narrow dark vertical bars across the middle sides, and males have an irregular pattern of dark blotches on the caudal peduncle. The barred pattern resembles that of species of *Crenicichla* from the upper Paraná drainage. Among those species, *C. jupiaensis* is notable for its numerous narrow vertical bars extending all the way from the dorsal fin base to the lower side. *Crenicichla jaguarensis*, *C. haroldoi*, and *C. niederleini* have a distinct lateral band, but also narrow vertical bars crossing it. Like *C. mucuryna*, Paraná species have fairly low

scale counts, E1 row scales ranging from 47–65, contrasting with the other species of the *C. lacustris* group (63–70, rarely fewer than 60). The sexual dimorphism is similar to that reported for *C. missioneira* and related species, in which males have a spotted caudal peduncle, but not females (Lucena & Kullander, 1992). However, in *C. mucuryna*, the irregular spots on the caudal peduncle represent homologues of the more anterior vertical bars.

Further comparison of *C. mucuryna* with the remaining coastal species of the *C. lacustris* group seems unwarranted, but the species should be reconsidered in a revision of the barred *Crenicichla* species from the Paraná drainage. The pattern of narrow bars may provisionally be taken as a synapomorphy, although vertical bars occur in a larger group of *Crenicichla*. It is notable that *C. mucuryna* only occurs in the upper rio Mucuri and is not syntopic with other species of *Crenicichla*. We believe that the upper Mucuri may represent an old part of the Paraná drainage, which was diverted to an Atlantic drainage and has remained isolated, but we are unable to propose a detailed historical scenario, especially since the Mucuri now is margined by coastal drainages with only species of the *C. lacustris* group, and the São Francisco drainage which has only species of the *C. lepidota* group. A large number of non-cichlid species were collected in association with *C. mucuryna* that seem for the most part to represent common coastal taxa at species or genus level.

Fig. 2. Collecting localities of *Crenicichla lacustris* and *C. mucuryna* in the coastal rivers of eastern Brazil. Most important rivers are: 1. Rio Paraíba do Sul; 2. Rio Doce; and 3. Rio Jequitinhonha. A symbol may cover more than one collecting site.

Crenicichla lacustris (Castelnau)

Figs. 3–4

Diagnosis. An elongate, large sized species of the *C. lacustris* group, distinguished from all other coastal southeastern Brazilian species by its color pattern. Lateral band continuous from head to caudal fin base, vs. subdivided into a series of blotches in *C. punctata* and *C. maculata*; suborbital stripe short and narrow, occasionally obsolete, vs. wide and prominent in *C. iguapina*; small dark spots on side of head present, vs. absent in *C. tingui*; in *C. tingui* both males and females have side of body spotted, though in males spots not extending onto abdominal side and lateral band remaining prominently pigmented, whereas in *C. lacustris* males lateral band indistinct in combination with dark spot pattern. From other species of the *C. lacustris* group, *C. lacustris* can be distinguished by E1 row scales count, 60–75 (vs. 47–65) and presence (vs. absent) of small dark spots on side of head present.

Description. Based primarily on specimens over 100.0 mm. Largest male 235.0 mm, largest female 290.0 mm. Measurements given in Table 1, counts in Tables 4–8. See Figs. 3–4 for general aspect.

Comparatively elongate, body depth 18.6–23.9% SL. Head about as deep as wide or slightly deeper than wide. Caudal peduncle longer than deep. Snout long, rounded when viewed from above, pointed in lateral view. Lower jaw prognathous.

Fig. 4. *Crenicichla lacustris*, female, USNM 318218, 171.0 mm SL, rio Buranhem, State of Bahia, Brazil.

Ascending premaxillary process reaching to 1/2 of orbit. Maxilla reaching to vertical from anterior margin of orbit. Upper lip thick and wide, folds not continuous but cutting into symphyseal wide thickening. Postlabial skin fold margin truncate or slightly rounded. Orbit supralateral, not visible from below, chiefly in anterior half of head. Nostrils dorsolateral, about halfway between orbit and margin of postlabial skin fold and with low tubular margin but no anterior marginal skin flap. Preopercle regularly serrated.

Flank scales strongly ctenoid. All scales on head, anteriorly on back, along dorsal fin base, chest, and on belly below line from lower edge of pectoral axilla to anal fin origin and along anal fin base cycloid. Predorsal scales small, superficially embedded in skin, extending forward almost to transverse frontal lateralis canal. Prepelvic scales very small, superficially embedded in skin. Cheek fully scaled or narrowly naked ventrally and anteroventrally; 7-11 rows of scales below eye, embedded in skin. Interopercle naked. Circumpeduncular scale rows 11-15 dorsally, 12-16 ventrally (total 28-33, including lateral lines).

Scales between upper lateral line and dorsal fin base 9-12 anteriorly, 4-6 posteriorly; 3-4 scale rows between lateral lines. Anterior upper lateral line scales slightly larger and more elongate than adjacent scales, remaining lateral line scales nearly same size as adjacent scales; 3 scales impinging on each scale of anterior part, 2 on each scale of posterior part of upper lateral line; 2 scales impinging on each scale of lower lateral line. Scales absent from dorsal, anal, pectoral, and pelvic fins. Caudal fin squamation concave, marginally extending beyond middle of fin.

First dorsal spine about 1/3-1/4 length of last; spines increasing in length to last but subequal from about 10th. Soft part of dorsal fin pointed; both sexes sometimes with produced middle rays, reaching to about base of caudal fin. Soft anal fin with acuminate tip; not reaching to caudal fin base in both sexes. Caudal fin rounded. Pectoral fin rounded, reaching about halfway to anal fin origin. Pelvic fin inserted well posterior to vertical from pectoral axilla, with acuminate tip, second ray longest, reaching about halfway to anal fin origin; anterior rays and margin thickened.

All teeth pointed, slightly recurved. Outer row of teeth distinctly larger than inner teeth and larger anteriorly than posteriorly. Upper jaw with 4-5 inner rows; all teeth depressible. Lower jaw anteriorly with 3 inner rows; all teeth inclinable or depressible.

Microbranchiospines present externally on second through fourth gill arches.

Coloration in alcohol. Yellowish to brownish, darker on back, whitish on belly, with brown or black markings. Lateral line scales light. Upper lip gray. Dark brown preorbital stripe from orbit to margin of mouth. Dark brown postorbital stripe running straight from orbit to dorsal end of gill cleft, sometimes reduced to blackish spot immediately posterior to orbit. Nuchal markings very light in medium and large specimens. In specimens up to 116 mm (MNRJ 13394) sometimes with

black blotch along posttemporal and dark band along margin of predorsal scales above sphenotic.

Suborbital stripe black, never extending below middle of cheek, and sometimes reduced to small spot at orbital margin. Occasionally ends in few dots scattered down cheek for three or four scales. Suborbital stripe better developed in females than in males. Males with body covered with seemingly irregularly scattered blackish spots, except for ventral part of abdomen. Such spots found also on opercle and subopercle and posteriorly on cheek. Small specimens (to ca. 75 mm), however, lack spots on head. Females have spots on body or completely lack body spots. Both sexes with wide horizontal dark stripe extending from gill opening to end of caudal peduncle, restricted to area between lateral lines, but generally more distinct in females. Females also generally show 5-7 well expressed vertical bars extending from lateral band to dorsal fin base, and another two dark blotches across dorsal margin of caudal peduncle.

Dorsal fin in females smoky with wide dark margin and sometimes with distinct light submarginal stripe. Most females with slightly elongate, ocellated black blotch with white margin on middle portion of dorsal fin, usually between 13th and 17th or 12th and 17th spines; one female (USNM 318218) show ocellus between 11th and 14th spines and another small one between 14th and 17th, in small females blotch sometimes indistinct and without clearly defined light margin. Soft portion of dorsal fin may feature few dark dots. Males with dorsal fin grayish with numerous dark spots irregularly distributed over both spinous and soft portions.

Anal fin grayish; males with numerous dark spots on posterior membranes; in females anal fin immaculate or with only few dark spots. Pelvic fins whitish. Females with only few dark spots on caudal fin. Caudal fin of males vividly patterned with dark dots. Rounded caudal spot black and ocellated. One male specimen (MNRJ 14394) with dark dots between pectoral fin rays, otherwise pectoral fin immaculate.

Color in life. Two large adults, male and female, ca. 220 and 230 mm, from lagoa de Juturnaiba, State of Rio de Janeiro, collected July 1981 and photographed freshly preserved, similar to preserved specimens. However, dark spots on side and head maroon, more reddish in male, and female with orange horizontal stripe along side of abdomen adjacent to lateral band. Lateral band conspicuous in both specimens. Young female from rio do Salto, Macaé, State of Rio de Janeiro, collected 28 January 1997 also with well marked lateral band and many large reddish spots on sides and gill cover.

Variation. Data is given separately here for the sample from the rio Doce lakes. These specimens are in a poor state of preservation and the only two specimens sexed are definitely females. These specimens differ from other *C. lacustris* in having a longer snout, a more prognathous (and longer) lower jaw, and a modal anal fin count of III,8 rather than III,9. None of the specimens features a lateral band, as is always evident in female *C. lacustris* from elsewhere and commonly also apparent

at least as a trace in males. Instead both sexes have spots all over the body, the females also featuring dark spots on the gill cover. Although Menezes (1987) was able to distinguish the sympatric rio Doce *Oligosarcus* as a species distinct from the species of *Oligosarcus* in the Paraíba do Sul and coastal plain, we hesitate to give species status to the rio Doce *Crenicichla* for want of well preserved material that would enable us to provide a useful diagnosis. With the material at hand, the overlap of counts and meristics prevents us from a satisfactory diagnosis, and the state of preservation makes a proper evaluation of the color pattern equally unsatisfactory.

Stomach contents. Two stomachs examined, DBAV 0426 (154.2 mm) and MNRJ 14390 (84.8 mm), contain fish remains.

Geographical distribution. Collections range from coastal rivers from rio Buranhem south to rio Paraíba do Sul, including the rio São João drainage in the State of Rio de Janeiro (Fig. 2). There is one population in the lakes of the upper rio Doce, but otherwise no material is available from the upper rio Doce valley. The species apparently occurs all along the rio Paraíba do Sul downstream from the area of Resende. The species is absent from the rio Mucuri, which is within the total range of *C. lacustris*.

Notes. The two syntypes of *C. lacustris* were reported by Castelnau to come from Bahia (= Salvador, State of Bahia). As no *Crenicichla lacustris* group species has been found again further north than the rio Buranhem, we find it likely that the locality given by Castelnau is in error. Castelnau lived in Salvador as the French Consul in 1849 and wrote the multivolume itinerary of his South American travels in that period (Papavero, 1975). Circumstantial evidence suggests, however, that no *C. lacustris* group species occur in the Salvador area, and that the syntypes of *C. lacustris* most likely came from near Rio de Janeiro where Castelnau stayed from 17 June till 13 October 1843.

Recent extensive collecting efforts in the rio Jequitinhonha and rivers from the Jequitinhonha north to include the rio Paraguaçu (by J. Garavello, S. Jewett and R. Macedo, and R. E. Reis *et al.*) failed to locate any *Crenicichla* material. The Buranhem specimens (the next river south from the Jequitinhonha south) reported herein likely are the most northern *Crenicichla* treated here, and they conform to *C. lacustris*.

Castelnau made his most important collecting trip in South America in 1843, starting from Rio Janeiro, travelling along the Tocantins, then west to Peru and finally down the Amazon and through to Guyana from where he returned to France in 1847.

Castelnau (1855) reported mostly on marine fishes observed or collected at Salvador and Rio de Janeiro, and freshwater fishes mostly collected or observed in the Araguaia and in Peru, and in inland Minas Gerais. One species is explicitly reported from Rio de Janeiro, viz. *Loricaria castanea* (p. 46, currently in the genus *Loricariichthys*). *Erythrinus trahira* (presumably an *Hoplias* species) is reported as common in the fresh waters around Salvador (p. 56), *Chromys paraguassu*

and *C. obscura*, representing a single valid species of *Geophagus*, are described from the rio Paraguaçu, which has its mouth at Salvador. *Chalceus devillei* (p. 69; now in the genus *Brycon*) and *Tetragonopterus vittatus* (p. 66) are described as new species from Bahia, and *Xiphorhynchus hepseticus* Müller & Troschel is reported (p. 75) from Bahia.

Howes (1982) redescribed *Brycon devillei*, emphasizing the distinctiveness of the species. Howes tentatively included material from the rio Jequitinhonha (*Brycon insignis* Steindachner) and rio Doce. Another species described from 'Bahia', viz. *B. bahiensis* Günther, is apparently known only from the type specimen and one other more specimen from Rio de Janeiro (Howes, 1982). Lima (2003) assigned it as a synonym of *Brycon opalinus* (Cuvier), a species with the type locality Rio de Janeiro. Howes (1982) grouped *B. devillei* with *B. acuminatus*, *B. ferox*, and *B. reinhardti*.

Brycon ferox Steindachner is known only from the type material collected in the rio Mucuri. Howes (1982) thought that it might be the same as *Brycon acuminatus* (Eigenmann & Norris) (synonym of *B. insignis* Steindachner in Lima, 2003), known only from two specimens, both collected in the rio Tietê, a tributary of the Paraná (but the type locality was erroneous, the holotype apparently being collected in the rio Paraíba do Sul, see Howes, 1982 and Lima, 2003).

According to Lima (2003) *Brycon reinhardti* Lütken occurs in the São Francisco (rio das Velhas) and is assigned as a synonym of *B. nattereri* Günther (Paraná river basin).

Tetragonopterus vittatus is an *Astyanax bimaculatus*-like species, treated as a subspecies of *A. bimaculatus* by Fowler (1948) and later a provisional synonym of that species by Lima *et al.* (2003). It was reported from many localities near Salvador by Eigenmann (1921).

Menezes (1987) included Castelnau's *Xiphorhynchus hepseticus* in his *Oligosarcus acutirostris*, which was reported from many localities between the mouth of the rio Jequitinhonha south to the rio São José das Torres, State of Espírito Santo, where it is replaced by *O. hepsetus*, which ranges all the way to the rio Cubatão in Santa Catarina.

Whereas from the above there is little doubt that Castelnau had freshwater fish collections from Bahia (better understood as the present city of Salvador than as the "State of Bahia"), viz. specimens of *Geophagus*, *Brycon devillei*, and *Astyanax vittatus*, it is equally clear that he had freshwater fish collections from Rio de Janeiro (*Loricariichthys castaneus*).

We find it likely that the '*X. hepseticus*' did not come from Salvador since there are no *Oligosarcus* north of the Jequitinhonha. Indeed, given that Castelnau had collections from Rio de Janeiro, it may have come from there rather than from Bahia, and represent *O. hepsetus* rather than *O. acutirostris*. Menezes did not examine Castelnau's specimens and may have relied entirely on the locality for the identification.

It is therefore possible that the *Crenicichla lacustris* came from somewhere near Rio de Janeiro. There is no indication or evidence known to us that Castelnau sampled along the coast between Rio de Janeiro and Bahia.

Crenicichla dorsocellata is based on the holotype from

Campos and a paratype from Santarém, in the Amazon drainage. The latter has since been identified by most authors as a member of the *C. wallacii* group which is common in the Amazon basin, and also features a prominent dorsal fin ocellus. *Crenicichla dorsocellata* falls within the variation of *C. lacustris* as here understood, and is therefore synonymized with that species.

Crenicichla biocellata was described from two specimens, one from rio Doce, collected by E. Garbe in 1906 and expressly referred to as the type; the other specimen was from Porto Cachoeiro, collected by E. Garbe in 1912. The type material of *C. biocellata* was not listed by Miranda Ribeiro (1918) in his catalogue of fishes in the Museu Paulista (presently MZUSP). Britski (1969: 210) listed the paratype (MZUSP 1781), noting that Porto Cachoeiro had meanwhile changed its name to Santa Leopoldina and is situated on the rio Santa Maria da Vitória and not on the rio Doce as stated in the original description. Ploeg (1991) also listed this paratype, but as the holotype. Actually, the holotype was present in the MZUSP but went undetected until we were able to identify it with the help of O. Oyakawa as a specimen of 215 mm total length in a lot of two specimens (MZUSP 1167), with collecting data as the lower rio Doce, E. Garbe 1906. The specimen conforms to Ihering's description and has been separated as the holotype of *C. biocellata*, with the catalogue number MZUSP 1167.

We have not found any clear evidence of a specific distinctness of coastal plain material representing the nominal taxon *C. biocellata* and *C. lacustris* from the rio Paraíba do Sul and therefore synonymize *C. biocellata* with *C. lacustris*.

Whereas in preserved specimens males and females differ in the extent of the spotting of the sides, it appears as if the reddish spots of females are lost, whereas in males they are retained in preservative probably because they are underlain by more persistent melanophores. These diagnostic spots are likely a part of the breeding color pattern, unlike the head spots found in *C. punctata*, which are persistent in preservative and relatively smaller. Inasmuch as the other coastal species lack corresponding spots, the red spots on the gill cover, and perhaps those on the anterior body sides, are probably autapomorphic for *C. lacustris*.

Crenicichla iguapina, new species

Fig. 5

Holotype. MZUSP 49062. Young male, 126.2 mm. Brazil, State of São Paulo, rio Ribeira de Iguape drainage, Iporanga, rio Betari, Oct 1961, H. Britski and N. A. Menezes.

Paratypes. 12 specimens, 63.5–176.3 mm, all from State of São Paulo, rio Ribeira drainage. MCP 18241 (2, 110.2–137.2 mm), rio Ribeira, mun. Ribeira, 10 Nov 1991, C.R. Bizerril; MNRJ 6318 (2, 127.6–159.8 mm), rio Tijuco, 200 meters from confluence with rio Ribeira, mun. Ribeira, 28 Jan 1953, E. Travassos & H. Travassos; MZUSP 2530 (2, 141.6–164.4 mm), ribeirão Poço Grande, tributary of the rio Juquiá, mun. Juquiá, 1898; MZUSP 35308 (1, 88.8 mm), ribeirão Grande, bairro Jaraçatiá, mun. Miracatu, 29 Jul 1985, O. Oyakawa. MZUSP 36540 (1, 89.4 mm), stream tributary of the

ribeirão Fundo, between km 15 and 16 of the road Juquiá-Sete Barras, mun. Juquiá, 12 Oct 1985, O. T. Oyakawa; MZUSP 37908 (1, 158.5 mm), rio Ribeira de Iguape, mun. Registro, 12 Sept 1978, V. Lobão; MZUSP 40213 (1, 176.3 mm), rio Pariqueira-Mirim, sitio Margom, mun. Registro, 16 Aug 1985; MZUSP 41204 (1, 63.5 mm), ribeirão Poço Grande, fazenda Poço Grande, mun. Juquiá, 5 Sep 1969, H. Britski and J.C. Garavello; MZUSP 41208 (1, 105.1 mm), rio Ribeira de Iguape, mun. Registro, 17 Feb 1956, Miguel Cuocolo.

Diagnosis. An elongate, medium sized species of the *C. lacustris* group distinguished from other species of *Crenicichla* along the southeastern Brazilian coast by possession of a continuous dark band along middle of side from which five paler dark bars extend to dorsal fin base, and another one or two bars to dorsal margin of caudal peduncle. Light areas present between those bars. Distinguished from *C. lacustris* and *C. tinguí*, with similar color pattern, by absence of dark spots on side of head (*vs.* present in *C. lacustris*) and presence of a conspicuous suborbital marking (reduced to a small spot little below orbit and at most two more small spots below that spot in *C. tinguí*). From *C. haroldoi*, *C. jaguarensis*, and *C. jupiaensis*, *C. iguapina* can be distinguished by E1 row scales counts, 60–68 (*vs.* 47–56); and from *C. iguassuensis* by having a continuous dark band along middle of side (*vs.* absent). *Crenicichla iguapina* differs from *C. niederleini* by absence of narrow vertical bars crossing dark lateral band (*vs.* present).

Description. Based primarily on specimens over 100.0 mm. Largest male 159.8 mm, largest female 158.5 mm. Measurements given in Table 2, counts in Tables 4–8. See Fig. 5 for general aspect.

Comparatively deep bodied, depth 18.8–22.1% SL. Head about as deep as wide or slightly wider than deep. Caudal peduncle longer than deep. Snout long, rounded when viewed from above, pointed in lateral view. Lower jaw prognathous. Ascending premaxillary process reaching to vertical from middle of orbit. Maxilla reaching to vertical from anterior margin of orbit or not quite so far. Upper lip thick and wide, folds not continuous but cutting into symphyseal wide thickening. Postlabial skin fold margin truncate or rounded. Lower lip fold interrupted at 4/5 distance to jaw tip. Orbit supralateral, chiefly in anterior half of head, eyes not visible from below. Nostrils dorsolateral, about halfway between orbit and margin of postlabial skin fold or closer to orbit, with low elevated margin, anterior marginal skin flap absent. Preopercle regularly serrated.

Flank scales strongly ctenoid. All scales on head, anteriorly on dorsum, close along dorsal fin base, on chest, and on belly below line from lower edge of pectoral axilla to anal fin origin and along anal fin base cycloid. Predorsal scales small, superficially embedded in skin, extending forward to transverse frontal lateralis canal. Prepelvic scales very small, superficially embedded in skin. Cheek fully scaled or narrowly naked ventrally and anteroventrally; 8–9 scales rows below eye, embedded in skin. Interopercle naked. Circumpeduncular scale rows 11–13 dorsally, 12–15 ventrally (total 26–30, including lateral lines).

Table 2. Morphometry of *Crenicichla iguapina* and *C. tingu*. n= number of specimens; SD= Standard deviation.

Measurement	<i>C. iguapina</i>					<i>C. tingu</i>

Lower jaw length	13	13.5	17.7	15.4	1.350	9	13.8	16.2	15.4	0.767	

Scales between upper lateral line and dorsal fin 8-11 anteriorly, 4-5 posteriorly; 3 scale rows between lateral lines. Anterior upper lateral line scales slightly larger and more elongate than adjacent scales, remaining lateral line scales nearly same size as adjacent scales; 3, occasionally 4 scales impinging on each scale of anterior portion, two on each scale of posterior portion of upper lateral line; 2 scales impinging on each scale of lower lateral line. Scales absent on dorsal, anal, pectoral, and pelvic fins. Caudal fin squamation slightly concave, marginally extending to middle of fin.

First dorsal spine about 1/3-1/4 length of last; spines increasing in length to last but subequal from about 10th. Soft part of dorsal fin rounded or pointed; both sexes sometimes with produced middle rays reaching to about base of caudal fin base. Soft anal fin with rounded or acuminate tip, not reaching to base of caudal fin. Caudal fin rounded. Pectoral fin rounded, reaching about halfway to anal fin origin. Pelvic fin inserted well posterior to vertical from pectoral axilla, with subacuminate tip; second ray longest, reaching halfway to anal fin origin; anterior rays and margin thickened.

All teeth pointed, moderately to strongly recurved. Outer row teeth distinctly larger than inner teeth and larger anteriorly than posteriorly. Upper jaw anteriorly with 4-5 inner rows; outer row teeth moveable, inner teeth inclinable or fully depressible. Lower jaw anteriorly with 3 inner rows; all teeth inclinable or depressible.

Microbranchiospines present externally on second to fourth gill arches.

Coloration in alcohol. Sexes differ in relative expression of body and fin markings: principally males with vividly spotted sides and fins, females mostly immaculate save for caudal spot. Dark brown preorbital stripe running from orbit across upper lip and around tip of lower jaw. Dark brown postorbital stripe running straight from orbit to dorsal end of gill cleft, sometimes reduced to blackish spot immediately posterior to orbit. Nuchal markings faint in large specimens, and include black spot slightly above posttemporal and triangular spot at middle of distal extrascapular. Suborbital stripe dark brown to black spot on

second infraorbital, continuous with brown confluent dots on scales below, extending to 3/4 or 4/5 distance to preopercle; narrow in males, wide and even slightly widened distally in females; sometimes fragmented into dots on scale centres distally. Lateral line scales light with dark dot distally.

Males with numerous small dark spots scattered over middle sides and onto back. No spots on head. Holotype with spots still largely restricted to band between levels of lateral lines. Females with few spots only, or spots completely wanting from sides. Dark band along middle of side persist in females and 6 vertical dark bars descending from dorsal fin base to band enclose lightened areas over course of lateral line.

In males dorsal fin grayish with up to 6 (spinous) or 8 (soft portion) horizontal rows of dark spots. Dorsal fin in large females smoky with darker wide margin, sometimes with distinct light submarginal stripe. Dark, light-ringed spot located on middle portion of dorsal fin between 13th and 17th or 12th and 17th spines; one female (MZUSP 37908) features two ocellar spots, one between 11th and 14th spines, another between 14th and 16th spines. Soft portion of dorsal fin sometimes with few dark dots.

Anal fin grayish; in males up to four horizontal rows of dark spots on soft portion; in females anal fin immaculate or with few dark spots. Pelvic fins whitish.

In males caudal fin vividly patterned with up to 8 vertical rows of dark spots except for distal margin. Females with immaculate caudal fin or only few dark dots present. Caudal spot small, black, rounded and ocellated in both sexes; black portion extending between rays D1-D4 or V1-D3.

Smallest specimen available, 63.5 mm (MZUSP 41204), notably lacking suborbital spot or stripe, and flank spotting restricted to lateral band and dorsum. Dark spots on dorsal, anal and caudal fins arranged in lines. One row of spots along base of dorsal fin and another along middle of fin. On caudal fin dark spots arranged in three parallel vertical rows; distally along entire fin margin dark submarginal band followed by hyaline margin.

Young female, 89.4 mm (MZUSP 36540), with dark brown lateral band 3-4 scales deep, mainly between lateral line levels; scattered dark brown spots on side mainly located at lateral band and above. Dorsal fin with two rows of dark spots. Cau-

Fig. 5. *Crenicichla iguapina*, male, MZUSP 49062, holotype, 126.2 mm SL, Iporanga, rio Betari, rio Ribeira drainage, State of São Paulo, Brazil.

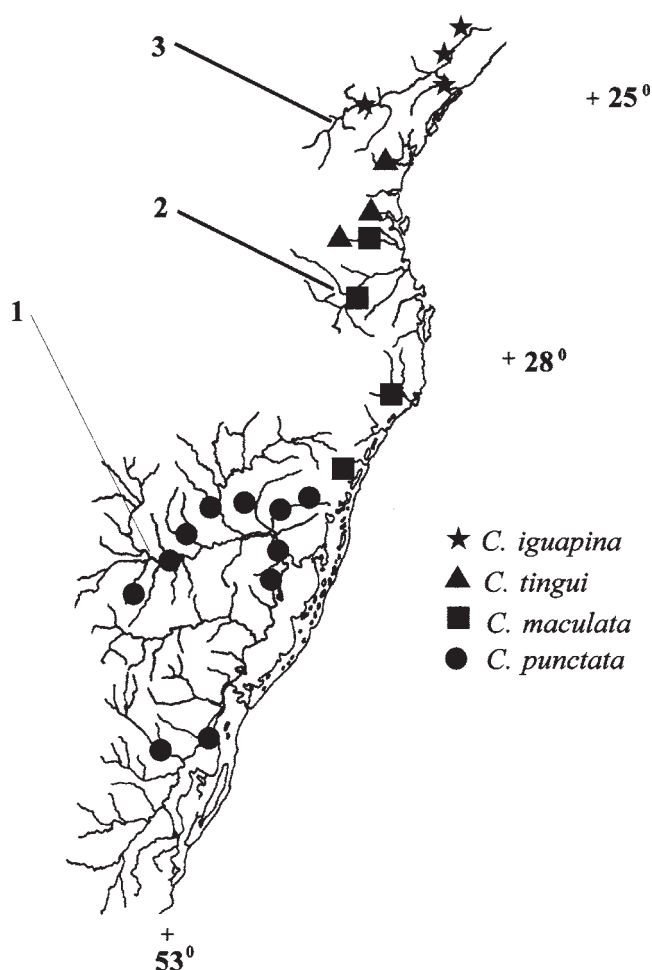

Fig. 6. Collecting localities of *Crenicichla iguapina*, *C. tingui*, *C. maculata*, and *C. punctata* in the coastal rivers of southeastern Brazil. Most important rivers are: 1. Rio Jacui (part of the laguna dos Patos System); 2. Rio Itajaí-Açu; and 3. Rio Ribeira de Iguape. A symbol may cover more than one collecting site.

dal fin with small, light ringed spot between rays D1 and D4, posteriorly 3 irregular vertical rows of brown spots; caudal fin posterior margin hyaline with wide gray submarginal band.

Stomach contents. Stomachs of two specimens examined, MZUSP 37908 (158.5 mm), and MZUSP 40213 (176.3 mm), empty. Radiographed specimen MNRJ 6318 (159.8 mm) shows fish remains.

Geographical distribution. Known only from the rio Ribeira de Iguape drainage in the State of São Paulo (Fig. 6).

Etymology. Named for the river drainage in which the species appears to be endemic, the rio Ribeira de Iguape. The name is an adjective with alternative endings *-inum* and *-inus*.

Notes. The occurrence of *C. iguapina* in the rio Ribeira de Iguape reinforces the concept that this drainage is an important area of endemism. Despite the scarcity of taxonomic revisions of its fish fauna, many species have been reported exclusively from that drainage viz. *Neoplecostomus ribeirensis* (Langeani, 1990), *Otothyris juquiai* (Garavello *et al.*, 1998), *Isbrueckerichthys alipionis* and *I. duseni* (Pereira & Reis, 2002), *Kronichthys subteres* (Weber, 2003), *Pimelodella kronei* and *P. transitoria* (Bockmann & Guazzelli, 2003), and *Hypostomus agna* and *H. interruptus* (Oyakawa *et al.*, 2005).

Crenicichla tingui, new species

Fig. 7

Holotype. MCP 12606. Female, 98.0 mm. Brazil, State of Paraná, municipal border Paranaguá-Morretes, rio Jacarei below the bridge at km 18 of road BR-277 (25°35'S 48°43'W), 7 Feb 1988, P.A. Buckup, E. Pereira & P. Azevedo.

Paratypes. 10 specimens, 62.0–121.0 mm, all from Brazil. Santa Catarina: MCP 6909 (2, 98.9–121.0 mm), arroio Lindo at road BR-280, Pirabeiraba, mun. Joinville, 26°13'S 48°54'30"W, 19 Sep 1985, C.A.S. Lucena *et al.*; MCP 19892 (1, 195.0 mm), rio Ano Bom, Itapocu drainage, mun. Corupá, 1 Aug 1997, Marcelo Aranha *et al.*; NMW 33286 (1, 92.0 mm), mun. Joinville, 1913, V. Berndt. Paraná:

MCP 16443 (1, 115.7 mm), rio dos Nunes, rio Cachoeira drainage, mun. Antonina, 25°25'25"S 48°43'35"W, 8 Jan 1993, J.M.R. Aranha *et al.*; FMNH 54137 (5, 62.0–112.0 mm), Morretes, ca. 25°28'S 48°51'W, 4 Jan 1909, J. D. Haseman (previously IUM 2702).

Diagnosis. An elongate, medium sized species of the *C. lacustris* group distinguished from all other coastal southeastern Brazilian species in color pattern. Lateral band continuous from orbit to caudal fin base, *vs.* subdivided into a row of blotches in *C. punctata* and *C. maculata*; suborbital stripe short and narrow, occasionally restricted to a small spot at orbital margin, *vs.* wide in *C. iguapina*; spots absent from side of head, *vs.* present in *C. lacustris*. The most similar species may be *C. lacustris*. In *C. lacustris* the lateral band tends to fade in males, giving way to spot pattern, and in females lateral band emphasized over spots. In *C. tinguí* band and spotting about equally expressed, although as in other species of the *C. lacustris* group, body and fin spots fewer and slightly lighter in females than in males of corresponding size. *Crenicichla tinguí* differs from all species of the *C. lacustris* group, except *C. iguassuensis*, by absence of narrow vertical stripes. *Crenicichla tinguí* can be distinguished from *C. iguassuensis* by lateral band continuous (*vs.* subdivided) and by suborbital stripe short and narrow (*vs.* elongate, extending to or nearly to preopercle).

Description. Based primarily on specimens over 100.0 mm. Largest male 121.0 mm, largest female 98.9 mm. Measurements given in Table 2, counts in Tables 4–8. See Fig. 7 for general aspect.

Comparatively elongate, depth 17.6–20.8%. Head about as deep as wide. Caudal peduncle longer than deep. Snout long, rounded when viewed from above, pointed in lateral view. Lower jaw slightly prognathous. Ascending premaxillary process reaching to vertical from middle of orbit. Maxilla reaching to vertical from anterior margin. Upper lip thick and wide, folds not continuous but cutting into symphyseal wide thickening. Postlabial skin fold margin truncate or slightly rounded. Lower lip fold interrupted at 4/5 distance to symphysis. Orbit supralateral, not visible from below, chiefly in anterior half of head. Nostrils dorsolateral, about halfway between orbit and margin of postlabial skin fold and with low tubular margin but no anterior marginal skin flap. Preopercle regularly serrated.

Flank scales strongly ctenoid. All scales on head, anteriorly on back, along dorsal fin base, on chest, and belly below line from lower edge of pectoral axilla to anal fin origin and along anal fin base cycloid. Predorsal scales small, superficially embedded in skin, extending forward almost to transverse frontal lateralis canal. Prepelvic scales very small, superficially embedded in skin. Cheek fully scaled or narrowly naked ventrally and anteroventrally; 6–9 scales rows below eye, embedded in skin. Interopercle naked. Circumpeduncular scale rows 12–13 dorsally, 12–15 ventrally (25–28 including lateral lines).

Scales between upper lateral line and dorsal fin 11–12 ante-

riorly, 4–5 posteriorly; 3 scale rows between lateral lines. Anterior upper lateral line scales slightly larger and more elongate than adjacent scales, remaining lateral line scales nearly same size as adjacent scales; three scales impinging on each scale of anterior part, two on each scale of posterior part of upper lateral line; 2 scales impinging on each scale of lower lateral line. Dorsal, anal, pectoral, and pelvic fins without scales. Caudal fin squamation concave, marginally extending to middle of fin.

First dorsal spine about 1/3–1/4 length of last; spines increasing in length to last but subequal from about 10th. Soft part of dorsal fin pointed; both sexes sometimes with produced middle rays, reaching to about base of caudal fin. Soft anal fin with acuminate tip; in both sexes not reaching to base of caudal fin. Caudal fin rounded. Pectoral fin rounded, reaching about halfway to anal fin origin. Pelvic fin inserted well posterior to vertical from pectoral axilla, with acuminate tip, second ray longest, reaching about halfway to anal fin origin; anterior rays and margin thickened.

All teeth pointed, slightly to strongly recurved. Outer row teeth slightly larger than inner teeth and larger anteriorly than posteriorly. Upper jaw anteriorly with 4–5 inner rows; outer row teeth movable, inner teeth inclinable or fully depressible. Lower jaw anteriorly with 3 inner rows; all teeth inclinable or depressible.

Microbranchiospines well developed, present externally on second to fourth gill arches.

Coloration in alcohol. Males and females similar in body color pattern, but males with more numerous and more distinct spots in unpaired fins. Dark brown preorbital stripe running from orbit across upper lip and around tip of lower jaw to dorsal end of gill cleft. Nuchal marks faintly expressed and including blackish spot slightly above posttemporal bone and dark band along margins of scales above sphenotic bone. Suborbital marking consisting of black spot on second infraorbital bone and brownish dots on one or two scales below, at best extending as pointed stripe down to middle of cheek as in holotype.

Wide blackish lateral band about four scales deep throughout or three scales deep anteriorly, running from pectoral girdle to caudal fin base, slightly separated from upper lateral line except at its end and extending ventrally onto scales of lower lateral line.

Five to seven dark vertical bars between dorsal fin base and upper lateral line, and two dark blotches sometimes discerned on dorsal part of caudal peduncle. Lateral line scales light with dark brown dot distally.

Minute black spots cover lateral band and posterior 3/4 of back in holotype; in others also in irregular horizontal row slightly ventral to lateral band. No dark spots on head other than those forming suborbital marking.

In males dorsal fin hyaline to whitish with dark spots along both spinous and soft portions, arranged in 2–3 horizontal rows anteriorly, 3–4 rows posteriorly; in females spotting distinct only posteriorly in fin. Anal fin hyaline or whitish with grayish lower margin and scattered dark dots more or less distinct in 2–3 horizontal rows on soft portion. Pelvic fin whit-

Fig. 7. *Crenicichla tingui*, female, MCP 12606, holotype, 98.0 mm SL, municipal border Paranaguá-Morretes, rio Jacarei, State of Paraná, Brazil.

ish. Caudal fin hyaline or whitish with seemingly irregularly distributed large gray dots, corners hyaline with dark sub-marginal band (not showing clearly).

Caudal spot conspicuous in specimens from Paranaguá catchment, large, extending between rays V1 and D5, deep black, rounded and margined with white ring, but less contrasted and appearing smaller in arroio Lindo sample. Pelvic and pectoral fins white and without marks.

Stomach contents. Single specimen examined, MCP 19892 (195.0 mm), contained chiefly remains of fishes.

Geographical distribution. *Crenicichla tingui* was collected in the rio Itapocu drainage and in small coastal rivers draining to the baía de Babitonga (rio Cubatão drainage) and the baía de Paranaguá (rio Jacarei and rio Cachoeira drainages) (Fig. 6).

Etymology. Tingui is a Tupi word used in southern Brazil to designate an origin or inhabitant of the State of Paraná. It is here used as a noun in apposition.

Notes. FMNH 54137 specimens were listed by Haseman (1911:351) as *Crenicichla lacustris*, with only the remark 'One has A. III, 10'.

Crenicichla maculata, new species

Fig. 8

Holotype. MCP 14661. Young female, 96.3 mm. Brazil, State of Rio Grande do Sul, Maquiné, rio Pinheiro, 14 Jan 1991, N. Menezes, R. Reis & E.H.L. Pereira.

Paratypes. 59 specimens, 61.8–211.5 mm. Santa Catarina: rio Tubarão drainage: MCP 11080 (5, 31.0–116.1 mm), rio Capivari road Gravatal-Armazém, 10 Dec 1986, C. Lucena *et al.* Rio Itajaí-Açu drainage: MCP 16479 (5, 83.6–116.6 mm), ribeirão São Luis, mun. Apiúna, 15 Oct 1993, C. Lucena *et al.*; MCP 16529 (3, 67.2–117.4 mm), same data as MCP 16479. Diagnosis. An elongate, large sized species of the *C. lacustris* group. *Crenicichla maculata* differs from all other coastal southeastern Brazilian species by the presence of a row of 5–8 dark blotches along middle of side and narrow vertical bars absent vs. presence of a continuous lateral band and vertical bars in *C. mucuryna*. *Crenicichla maculata* is most similar to *C. punctata* in color pattern, males always feature a pattern of irregularly distributed dark spots over the sides, whereas this pattern is lost in breeding females. *Crenicichla maculata* differs from *C. punctata* in absence of minute dark spots on the

Table 3. Morphometry of *Crenicichla maculata* and *C. punctata*. SD= Standard deviation.

head. From *C. haroldoi*, *C. jaguarensis*, and *C. jupiaensis*, *C. maculata* can be distinguished by E1 row scale counts, 60-75, one specimen with 58 (vs. 47-56). From *C. iguassuensis*, with similar color pattern, *C. maculata* differs by presence of a row of 5-8 dark blotches along side and snout pointed with lower jaw distinctly prognathous (vs. 4-5 dark blotches, snout blunt with lower jaw slightly prognathous). *Crenicichla maculata* differs from *C. niederleinii* by absence of narrow vertical bars.

Description. Based primarily on specimens about 100.0 mm and larger. Largest male 191.7 mm, largest female 211.5 mm. Measurements given in Table 3, counts in Tables 4-8. See Fig. 8 for general aspect.

Comparatively deep bodied, body depth 17.9-24.1% SL. Head nearly always slightly wider than deep, sometimes about as deep as wide. Caudal peduncle longer than deep. Snout long, rounded when viewed from above, moderately pointed in lateral view. Lower jaw prognathous. Ascending premaxillary processes reaching to vertical from middle of orbit. Maxilla reaching to vertical from anterior margin of orbit or slightly beyond. Upper lip thick and wide, folds not continuous but cutting into symphyseal wide thickening. Postlabial skin fold margin rounded. Orbit supralateral, eye not visible from below, chiefly in anterior half of head. Nostrils dorsolateral, about

halfway between orbit and margin of postlabial skin fold and with slightly elevated margin but no anterior marginal skin flap. Preopercle regularly serrated.

Flank scales strongly ctenoid. All scales on head, anteriorly on back to middle of upper lateral line, along dorsal fin base, on chest, and belly below line from lower edge of pectoral axilla to anal fin origin and along anal fin base cycloid. Predorsal scales small, superficially embedded in skin, extending forward to transverse frontal lateralis canal. Prepelvic scales very small, superficially embedded in skin. Cheek fully scaled or narrowly naked ventrally and anteroventrally; 5-9 scales rows below eye, embedded in skin. Interopercle naked. Circumpeduncular scale rows 11-14 dorsally, 11-15 ventrally (total 26-31 including lateral lines).

Scales between upper lateral line and dorsal fin 10-14 anteriorly, 4-7 posteriorly; 3 scale rows between lateral lines. Anterior upper lateral line scales slightly larger and more elongate than adjacent scales, remaining lateral line scales almost same size as adjacent scales; 3 scales impinging on each scale of anterior part, 2 on each scale of posterior part of upper lateral line; 2 scales impinging on each scale of lower lateral line. Scales absent from dorsal, anal, pectoral, and pelvic fins. Caudal fin squamation concave, marginally extending to middle of fin.

First dorsal spine about 1/3-1/4 length of last; spines in-

Fig. 8. *Crenicichla maculata*, female, MCP 14661, holotype, 96.3 mm SL, Maquiné, rio Pinheiro, State of Rio Grande do Sul, Brazil.

creasing in length to last but subequal from about 10th. Soft part of dorsal fin rounded or subacuminate, reaching to about base of caudal fin. Soft anal fin with rounded tip, not reaching to caudal fin base. Caudal fin rounded. Pectoral fin rounded, reaching halfway to anal fin origin. Pelvic fin inserted well posterior to vertical from pectoral axilla, with rounded tip, second ray longest, reaching halfway to anal fin origin; anterior rays and margin not particularly thickened.

All teeth pointed, slightly recurved. Outer row teeth distinctly larger than inner teeth and larger anteriorly than posteriorly. Upper jaw anteriorly with 4-5 inner rows; all teeth inclinable or depressible. Lower jaw anteriorly with 3 inner rows; all teeth inclinable or depressible.

Microbranchiospines present externally on second to fourth gill arches.

Lower pharyngeal tooth plate in 136 mm specimen, MCP 11257 (Fig. 9), strongly compressed dorsoventrally, slightly wider than long and with wide dentigerous area (length of bone including posterior muscular processes 93% of width, along midline 68% of width; dentigerous area length 76% of dentigerous area width; dentigerous area midline length 65% of dentigerous area width). Teeth fairly short laterally, gradually increasing in size caudally and medially, teeth in posterior row markedly longer than other teeth. On anterior half of bone and along margins unicuspid, pointed, with caudad curved tips; centrally rounded in cross section, with more or less central, worn cusp; posterior row teeth and few adjacent teeth with posterior rostrad curved cusp and subapical narrow shelf anteriorly. Posterior and posterolateral teeth more or less compressed in cross section, remainder rounded in cross section. 18 teeth in posterior row, 8-9 irregularly arranged teeth in midline row.

Coloration in alcohol. Dark brown preorbital stripe from orbit across upper lip and around tip of lower jaw. Dark brown postorbital stripe running straight from orbit to dorsal end of gill cleft, but sometimes reduced to blackish spot immediately posterior to orbit. Suborbital stripe as wide as pupil or slightly narrower, slightly caudad inclined, extending to or almost to margin of preopercle; proximally (on second infraorbital) entire, deep black, gradually more fragmented distally into blackish to brown spots on scale centers. Nuchal markings faint in larger specimens, but well marked in smaller specimens, including black spot little above posttemporal, spot occasionally elongated to form stripe along margin of predorsal squamation above sphenotic, and triangular spot at posterior middle of distal extrascapular.

Basic body pattern consisting of series of 5-8 dark brown to blackish, rounded or slightly elongated blotches along middle of side slightly below upper lateral line scale row, continued along caudal peduncle immediately above lower lateral line. Blotches as well as last blotch and caudal peduncle band connected by dark brown pigment given appearance of band with portions intensified. Blotches appear at irregular intervals, and another one or two blotches may appear interspersed between others or as a result of division of regular

spot. Slightly paler dark vertical bars extending between lateral blotches and dorsal fin base; often resulting in pattern of series of light blotches along sides of back. Lateral line scales light with dark dot distally.

Young specimens, males and most females with numerous minute dark spots irregularly distributed over body, excepting only head, chest, lower side of abdomen, along base of anal fin and ventrally on caudal peduncle. Breeding females completely lack minute dark spots. One male (MCP 11080, 114.4 mm), apparently in breeding color, overall light, with lateral blotches having nearly disappeared and conspicuous contrasting pattern of dark dots.

Unpaired fins marked with small, irregularly distributed dark spots, in about 3 (anteriorly) to 6 (posteriorly) horizontal rows on dorsal fin, up to about 7 vertical rows on caudal fin, and up to about 6 horizontal rows on anal fin. Caudal fin also with faintly expressed dark submarginal band along posterior margin. Caudal spot small, extending between rays D1 and D4, black, rounded or vertically ovate, usually with light margin only along margin toward caudal fin base, but sometimes fully ocellated. In young specimens spot fully ocellated, whereas in specimens understood as showing breeding color pattern light ring sometimes completely lost. Pelvic fin white and without markings.

In breeding females spots absent or few and indistinct in unpaired fins; dorsal fin in females smoky with darker wide margin, occasionally with distinct light submarginal stripe. Dark blotch or ocellus on middle portion of dorsal fin absent in all females.

Stomach contents. One specimen, 182.7 mm (MCP 15276) contained mostly mollusc shells (bivalves) but also coleopteran larvae. Another specimen, 191.7 mm (MCP 15275) contained remains of fishes and a gastropod mollusc.

Geographical distribution. Four areas of distribution are represented in our material. Most specimens come from a limited area north of laguna dos Patos, viz. the lower rio Maquiné, lower rio Três Forquilhas, lagoa dos Quadros, lagoa do Palmital and lagoa Emboaba, State of Rio Grande do Sul. To the north there is one sample from the rio Tubarão drainage, one from ribeirão São Luis in the rio Itajaí-Açu drainage, and another from the rio Itapocu drainage (Fig. 6) all in the State of Santa Catarina.

Notes. *Crenicichla maculata* is very similar to *C. punctata* and replaces *C. punctata* in drainages immediately north of the laguna dos Patos. The two species share a general color pattern consisting of a row of dark blotches along the middle of the side and numerous dark spots scattered over sides and fins. *Crenicichla maculata* can be distinguished by reference to the head coloration. In *C. punctata* both males and females have dark spots on the head similar to spots on the sides, but the spotting does not advance anterior to the first side blotch in *C. maculata*. Breeding females of *C. punctata*, however, may lack head spots and thus be indistinguishable from *C.*

Fig. 9. *Crenicichla maculata*, lower pharyngeal tooth plate in occlusal aspect, MCP 11257 (133.7 mm SL).

maculata specimens. The suborbital stripe is generally wider and longer in *C. maculata* (4–8 scales wide, extending to the preopercular margin) than in *C. punctata* (3–5 scales wide, extending to middle or 4/5 the distance to the preopercular margin), but several specimens remain unidentifiable using stripe width alone. There are no differences in fin or scale counts.

Crenicichla punctata Hensel

Fig. 10

Crenicichla punctata Hensel, 1870: 57 (Type-locality: aus dem Guahyba bei Porto Alegre ... Bächen des Urwaldes ... Waldbächen von der deutschen Colonie Sta. Cruz in Rio Grande do Sul).

Crenicichla polysticta Hensel, 1870: 58 (Type-locality: Rio Cadea des Urwaldes von Rio Grande do Sul).

Material examined. 67 specimens, 29.7–290.0 mm. Rio Grande do Sul: ZMB 7459 (1, 149.0 mm), rio Guaíba, mun. Porto Alegre, no date, R. Hensel, lectotype of *Crenicichla punctata*; ZMB 32679 (1, 90.4 mm), rio Guaíba, mun. Porto Alegre, no date, R. Diagnosis. An elongate, large sized species of the *C. lacustris* group. Similar to *C. maculata* and different from *C. tingui*, *C. iguapina*, and *C. lacustris* in having a row of about five dark blotches along middle of side, slightly separated from upper lateral line, followed by two often contiguous blotches, or forming a band, continuing blotch row on caudal peduncle. A pattern of irregularly distributed dark spots on flanks present in both sexes, but may be absent in breeding females. Different from *C. maculata* in presence of small dark spots on side of head, *vs.* absent. From remaining species in the *C. lacustris* group, *C. punctata* differs by absence of narrow vertical bars *vs.* present except in *C. iguassuensis*, and by presence of small dark spots on side of head of males *vs.* absence.

Description. Based primarily on specimens over 100 mm. Largest male 290.0 mm, largest female 225.0 mm. Measurements given in Table 3, counts in Tables 4–8. See Fig. 10 for general aspect.

Comparatively deep bodied, depth 19.0–26.3% SL. Head about as deep as wide or slightly deeper than wide. Caudal peduncle longer than deep. Snout moderately long, rounded when viewed from above, pointed in lateral view. Lower jaw prognathous. Ascending premaxillary process reaching to 1/3 of orbit. Maxilla reaching to vertical from anterior margin of orbit or, in large specimens, not quite so far. Upper lip moderately thick, folds not continuous but cutting into symphyseal narrow thickening. Postlabial skin fold margin rounded. Orbit supralateral, not visible from below, chiefly in anterior half of head. Nostrils dorsolateral, about halfway between orbit and margin of postlabial skin fold and with low tubular margin but no anterior marginal skin flap. Preopercle regularly serrated.

Flank scales strongly ctenoid. All scales on head, anteriorly on back, along dorsal fin base, on chest, and belly below line from lower edge of pectoral axilla to anal fin origin and along anal fin base cycloid. Predorsal scales small, superficially embedded in skin, extending forward to transverse frontal lateralis canal. Prepelvic scales very small, superficially em-

<i>C. punctata</i>	1		2		2	3	2	1	2	2	1	2		2	2			

bedded in skin. Cheek fully scaled or narrowly naked ventrally and anteroventrally; 6-9 scales rows below eye, embedded in skin. Interopercle naked. Circumpeduncular scale rows 12-13 dorsally, 11-14 ventrally (total 24-27, including lateral lines).

Scales between upper lateral line and dorsal fin 7-11 anteriorly, 4-5 posteriorly; scale rows between lateral lines 3. Anterior upper lateral line scales slightly larger and more elongate than adjacent scales, remaining lateral line scales nearly same size as adjacent scales; three scales impinging on each scale of anterior part, two on each scale of posterior part of upper lateral line; 2 scales impinging on each scale of lower lateral line. Dorsal, anal, pectoral, and pelvic fins without scales. Caudal fin squamation concave, marginally extending to middle of fin.

First dorsal spine about 1/3-1/4 length of last; spines increasing in length to last but subequal from about 10th. Soft part of dorsal fin pointed, reaching to about base of caudal fin or slightly beyond. Soft anal fin with subacuminate tip, not reaching to caudal fin base. Caudal fin rounded. Pectoral fin rounded, reaching halfway to anal fin origin. Pelvic fin inserted well posterior to vertical from pectoral axilla, with acuminate tip, second ray longest, reaching halfway to anal fin origin; anterior rays and margin slightly thickened.

All teeth pointed, slightly recurved. Outer row teeth distinctly larger than inner teeth and larger anteriorly than posteriorly. Upper jaw anteriorly with 4-5 inner rows; all teeth inclinable or depressible. Lower jaw anteriorly with 3 inner rows; all teeth inclinable or depressible.

Microbranchiospines present externally on 2nd to 4th arches.

Coloration in alcohol. Snout and dorsal surface of head anterior to predorsal squamation gray. Lower jaw, cheeks, and un-

derside of head yellowish or whitish. Dark brown preorbital strip from eye to tip of lower jaw. Dark brown postorbital stripe from eye to opercular tip, usually restricted to dark blotch between eye and preopercle. In few specimens pale blotch on posttemporal and also pale triangular spots on extrascapular series. Black suborbital stripe narrow, extending to middle or 4/5 distance to preopercle, proximally entire, distally or for most of length with pigmentation on scale centers deeper.

Both sexes with sides, dorsum, dorsal and anal fins covered with numerous irregularly distributed dark spots, all smaller than pupil. Spot pattern extends onto nape and sides of head, including gill cover and posterior half of cheek. Spots sometimes absent from head and most of body sides in females, probably as part of breeding color pattern.

Five wide dark vertical bars extending down from dorsal fin base, all except first and occasionally fifth divided into two bars. Bars ending in row of dark brown, usually slightly vertically extended or square blotches running between upper lateral line scales and E1 row, with two often contiguous blotches continuing row on caudal peduncle. Blotches vary in number, depending on whether divided like vertical bars or bridging two vertical bars

Dorsal fin in breeding females smoky with wide darker margin, sometimes with distinct light submarginal stripe. Some females with large black, slightly horizontally extended spot between dorsal spines 13th-18th or 12th-17th, in one female very large dark spot between spines 14 and 20 and continuing on the soft rays; spot narrowly margined by hyaline zone. Soft portion of dorsal fin sometimes with few dark dots. In males, non-breeding females, and young, dorsal fin grayish with 3 (anteriorly) to 5 (posteriorly) irregular rows of dark spots.

<i>C. punctata</i>		1						1	1	1				1	2	4	1							1	3	2				1													

Anal fin grayish; in large males with numerous dark spots on posterior membranes; in young specimens and females only few dark spots distally. Pelvic fins whitish. Breeding females with immaculate caudal fin or only few dark dots. In males caudal fin vividly patterned with dark dots except posterodistally. Caudal spot black, rounded, situated between rays D1 and D4, and margined by light ring. Lateral line scales light with dark dot distally.

Small specimens up to 34.0 mm with dark band along middle of side, continuing postorbital stripe to caudal fin base. From this band 6-10 dark vertical bars extending dorsally to dorsal fin base or dorsal margin of caudal peduncle. Nuchal markings conspicuous, including two dark spots anterior to extrascapular series. Posttemporal spot black and conspicuous. Lateral spotting hardly evident and concentrated to lateral band area; spots absent from head. In specimens 47.0 mm, few dark spots appear on opercle; specimens over 60 mm with well evident spots on head.

Stomach contents. Stomachs examined contained mollusc shells (bivalves) (MCP 11121, 149.6 mm) and aquatic insect larvae (MCP 13510, 199.6 mm).

Geographical distribution. Laguna dos Patos system, including the lagoa Mirim basin (Fig. 6).

Notes. *Crenicichla punctata* was redescribed by Lucena & Azevedo (1989), who included *C. polysticta* in the synonymy. Although they did not comment further on this act, in so doing they acted as first revisers (ICZN, Art. 24), giving the name *C. punctata* priority over *C. polysticta*.

Neither Lucena & Azevedo (1989) or we have examined the type series of *C. polysticta*. Hensel goes into such detail that we see no reason to doubt its identity with *C. punctata*. One of the syntypes, ZMB 7461, was figured by Ploeg (1991: fig. 160)

Table 8. Vertebrae count frequencies in species of *Crenicichla* from southeastern Brazil.

Abdominal	19	19	19	20	20	20	21	21
Caudal	17	18	19	17	18	19	17	18

<i>C. tingui</i>		2			3			1
<i>C. maculata</i>		1	1	3	12	6		3
<i>C. punctata</i>		1			2			

and fully agrees with *C. punctata*. Although Ploeg (1991: 12) states that the specimen (ZMB 7461) figured by him as *C. polysticta* is the ‘single known specimen’ and labels it holotype, it is clear from Hensel’s description that it is based on the large specimen, 225 mm, and one smaller specimen of 120 mm. The other syntypes cannot be located in the ZMB collection (H.-J. Paepke, *in litt.*, 13 Sep 1996). Ploeg (1991) included *C. punctata* in *C. lacustris* and figured the syntype, ZMB 7459 (Ploeg 1991: fig. 154), designated as lectotype of *C. punctata* by Lucena & Azevedo (1989: 90). *Crenicichla punctata* is most similar to *C. maculata* and compared with that species above.

Discussion

The six species of *Crenicichla* distributed along the southeastern Brazilian coast fall into three distinct morphological groups: *Crenicichla mucuryna* is a relatively small species with a low scale count (56–63 in E1 row) and a color pattern dominated by narrow vertical bars, similar to Paraná drainage species, and may not be closely related to any of the other coastal species.

Crenicichla lacustris, *C. iguapina*, and *C. tingui* reach large sizes, especially *C. lacustris*, which attains 290 mm. These species, representing *C. lacustris* of authors, all have a wide lateral band along the side, like the majority of *Crenicichla* species, and males are richly spotted on body and fins. Scale counts range from 60–75 (one specimen 57). Their respective distributions are allopatric along the coast from rio Buranhem to Santa Catarina north of the laguna dos Patos drainage.

Crenicichla punctata and *C. maculata* reach large sizes, attaining 290 mm and 211.5 mm, respectively. Their combined distribution extends from the laguna dos Patos into Uruguayan tributaries of the laguna Mirim. Scale counts range from 56 to 75. They feature a row of blotches along the side instead of a lateral band, in which respect they resemble the *C. missioneira* group of species recently described (Lucena & Kullander, 1992) from the rio Uruguai drainage, particularly *C. igara* Lucena & Kullander, 1992 and *C. jurubi* Lucena & Kullander, 1992. Although they share a pattern of richly spotted body sides and fins with the *C. lacustris-iguapina-tingui* assemblage, and a similar sexual dimorphism with reduced spotting in females, a similar condition is found among *C. missioneira* group species. In *C. igara* and *C. jurubi* there is no sexual dimorphism in the extensive spotting; in *C. missioneira*, and *C. tendybaguassu* spotting is restricted to males and to the caudal peduncle.

The close similarity between *C. punctata* and *C. maculata* as expressed by characters in combination, and their vicarying

distributions suggest that they may be closely related, and the same hypothesis may be advanced for *C. tingui*, *C. iguapina* and *C. lacustris*. The information available does not support and further relationship hypotheses, and the *C. punctata* and *C. lacustris* groups must be analysed with regard to a larger group of taxa and particularly the geographically close *C. scottii* and *C. missioneira* groups in the rio Uruguai drainage, and *C. iguassuensis*, and similar species in the rio Iguaçú drainage.

Species of the *C. punctata* and *C. lacustris* groups share with the *C. missioneira* and *C. igara* groups the presence of small dark spots covering the flanks and the associated sexual dimorphism of spotted males and immaculate or unspotted females. The presence of a series of dark blotches along the side is shared by the *C. punctata*, *C. missioneira*, and *C. igara* groups, and also with members of the *C. reticulata* group. We have identified one unique character of species of the *C. missioneira* and *C. reticulata* groups, *C. vittata* Heckel, 1840, and *C. celi-dochilus*. In these species, the females (in *C. celi-dochilus*, which is monomorphic, both sexes), have orange-red abdominal sides.

It is quite possible that the relationships of southeastern coastal drainage species have to be searched among various more interior *Crenicichla* groups which still have to be studied and which include several taxa with similar spot patterns in the rio Iguaçú and rio Paraná drainages. There is no indication that the *C. lacustris-iguapina-tingui* group would be most closely related to the *C. punctata-maculata* group; rather the pattern of blotches on the sides may be a synapomorphy of the *C. punctata-maculata* group with Uruguai and Paranaean species. As *C. mucuryna* is also distinct from remaining coastal species, we find it probable, and a subject of further investigation beyond alpha taxonomic, that the southeastern coastal *Crenicichla* fauna is derived from at least two different sources – Uruguai and Paraná drainages – and it may be incorrect to speak, in a historical view, of a particular ‘‘coastal’’ Brazilian fauna of *Crenicichla* species.

Several of the coastal Brazilian species of *Crenicichla*, most notably *C. mucuryna*, and *C. iguapina*, have very limited geographical distributions within areas that are among the most densely populated in Brazil and therefore may be considered as vulnerable. With the traditional classification at least four of the species (*C. lacustris*, *C. iguapina*, *C. maculata*, and *C. tingui*) would have been lumped under the name of *C. lacustris*. With improved taxonomic resolution, the conservation status of these species can be addressed with better precision.
